

COMPUTATIONS FOR MAZUR'S KNOT AND THE OCTAHEDRON

JACK CALCUT AND YANGYANG DU

ABSTRACT. We provide the code, complete output, and a brief analysis for every computer computation used in Sections 7 and 8 of our paper *Mazur's Knot and the Octahedron*.

1. INTRODUCTION

This is a companion paper to *Mazur's Knot and the Octahedron* [CD26]. It contains the code, complete output, and a brief analysis for every computer calculation used in Sections 7 and 8 of [CD26]. Together with the GitHub repository, this document makes those computations fully reproducible. All computations were performed using SageMath 10.7, SnapPy 3.3.2, and GAP 4.14.0. The code is available at <https://github.com/yyadu/Mazur-manifold-computation>.

We use the following notation consistent with our paper [CD26]:

K	Mazur knot in $S^1 \times S^2$
X	Mazur knot exterior
μ_K	Oriented meridian of K in ∂X
λ_K	Oriented longitude of K in ∂X
$X(p, q)$	Dehn filling of X using slope $(p, q) \leftrightarrow p/q$
M_k	Mazur 4-manifold with framing $k \in \mathbb{Z}$
∂M_k	Boundary 3-manifold of M_k
J	Jester knot in $S^1 \times S^2$
Y	Jester knot exterior
μ_J	Oriented meridian of J in ∂Y
λ_J	Oriented longitude of J in ∂Y
$Y(p, q)$	Dehn filling of Y using slope $(p, q) \leftrightarrow p/q$
N_k	Jester 4-manifold with framing $k \in \mathbb{Z}$
∂N_k	Boundary 3-manifold of N_k

ACKNOWLEDGMENT

The authors are grateful to Nathan Dunfield for invaluable conversations on SnapPy.

2. MAZUR AND JESTER KNOT EXTERIORS

The Mazur knot $K \subset S^1 \times S^2$ and the Jester knot $J \subset S^1 \times S^2$ are shown in Figure 1. Equipping K and J with the framing $k \in \mathbb{Z}$ yields the surgery diagrams for $\partial M_k = X(k, 1)$ and $\partial N_k = Y(k, 1)$ respectively in Figure 1.

Date: July 14, 2026.

FIGURE 1. Surgery diagrams for $\partial M_k = X(k, 1)$ (left) and $\partial N_k = Y(k, 1)$ (right).

We first import the link diagrams into SnapPy using the PLink editor.

```

1 import snappy
2 # Opens the PLink editor to draw links
3 M = snappy.Manifold()

```

- 1 Starting the link editor.
 - 2 Select Tools->Send to SnapPy to load the link complement.
 - 3 Your new Plink window needs an event loop to become visible.
 - 4 Type "%gui tk" below (without the quotes) to start one.
-

FIGURE 2. PLink Editor link diagrams for Mazur and Jester boundary 3-manifolds, together with their DT codes at the bottom.

The Dowker–Thistlethwaite (DT) codes for the two links in Figure 2 are

- DT: $[(14, 12, -16, -10, 18, -6), (-4, 2, 8)], [1, 1, 0, 0, 0, 1, 1, 0, 1]$
- DT: $[(10, -20, -16, 24, -14, 22, 18, -8, -4), (6, 12, -2)], [1, 1, 0, 1, 0, 0, 1, 1, 1, 0, 1, 0]$

The unknotted blue component is Dehn filled with slope $0/1 \leftrightarrow (0,1)$ to obtain the exterior X of K and Y of J respectively in $S^1 \times S^2$. The cusp shapes were computed geometrically in Section 6 of [CD26]. The SnapPy computations below provide an independent verification. We compute basic information about X .

```

1 import snappy
2 # Mazur knot exterior X
3 X = snappy.Manifold('DT: [(14,12,-16,-10,18,-6),(-4,2,8)], [1,1,0,0,0,1,1,0,1]')
4 X.dehn_fill((0,1),1)
5 X = X.filled_triangulation()
6 Xid = X.identify()
7 IsomX = X.symmetry_group()
8 print("Mazur knot exterior X")
9 print("Volume =", X.volume())
10 print("Isometric to census manifold:", Xid)
11 print("Cusp shape =", X.cusp_info('shape'))
12 print("")
13 print("Is X achiral?", IsomX.is_amphicheiral())
14 print("Order of isometry group =", IsomX.order())
15 print("Isometry group =", IsomX)
16 print("Self-isometries are:", IsomX.isometries(), "\n")
17 print("Isometries X -> m137 are:", X.is_isometric_to(snappy.Manifold('m137'),
18     return_isometries=True))

```

```

1 Mazur knot exterior X
2 Volume = 3.66386237670888
3 Isometric to census manifold: [m137(0,0)]
4 Cusp shape = [3.250000000000000 + 2.250000000000000*I]
5
6 Is X achiral? False
7 Order of isometry group = 2
8 Isometry group = Z/2
9 Self-isometries are: [0 -> 0
10 [1 0]
11 [0 1]
12 Extends to link, 0 -> 0
13 [-1 0]
14 [ 0 -1]
15 Extends to link]
16
17 Isometries X -> m137 are: [0 -> 0
18 [-1 -3]
19 [ 0 -1]

```

```

20 Extends to link, 0 -> 0
21 [1 3]
22 [0 1]
23 Extends to link]

```

Consequently:

- X is hyperbolic with $\text{vol}(X) \approx 3.66386$
- X is isometric to the 1-cusped census manifold $m137$
- The cusp shape of X is $\tau_X \approx \frac{13}{4} + \frac{9}{4}i$
- X admits no orientation reversing self-isometry
- The isometry group of X has order 2

SnapPy indicates the action of an isometry on cusps using 2×2 integer matrices. Each domain and target cusp torus must be equipped with an ordered homology basis $[\mu_D, \lambda_D]$ and $[\mu_T, \lambda_T]$ respectively. The matrix $A = \begin{bmatrix} a & c \\ b & d \end{bmatrix}$ implies that

$$x\mu_D + y\lambda_D \mapsto (ax + cy)\mu_T + (bx + dy)\lambda_T$$

In other words, the first column of A is the image of μ_D and the second column is the image of λ_D . If a manifold is defined in SnapPy as a link complement, then its cusps are equipped with standard topological meridian-longitude bases. This applies to X and Y , so ∂X is given the basis $[\mu_K, \lambda_K]$ and ∂Y is given the basis $[\mu_J, \lambda_J]$. Otherwise, SnapPy has its own heuristics for choosing bases of cusp tori. This applies to $m137$ and $t12072$.

From these conventions and the above computation we conclude:

- Every self-isometry of X acts trivially on slopes in ∂X
- Every isometry $X \rightarrow m137$ acts on slopes by $(p, q) \mapsto (p + 3q, q)$
- (Basis change) $X(k, 1)$ is homeomorphic to $m137(k + 3, 1)$ for each $k \in \mathbb{Z}$

We compute basic information about Y .

```

1  import snappy
2  # Jester knot exterior Y
3  Y = snappy.Manifold('DT: [(10,-20,-16,24,-14,22,18,-8,-4),(6,12,-2)], '
4      '[1,1,0,1,0,0,1,1,1,0,1,0]')
5  Y.dehn_fill((0,1),1)
6  Y = Y.filled_triangulation()
7  Yid = Y.identify()
8  IsomY = Y.symmetry_group()
9  print("Jester knot exterior Y")
10 print("Volume =", Y.volume())
11 print("Isometric to census manifold:", Yid)
12 print("Cusp shape =", Y.cusp_info('shape'))
13 print("")
14 print("Is Y achiral?", IsomY.is_amphicheiral())
15 print("Order of isometry group =", IsomY.order())
16 print("Isometry group =", IsomY)

```

```

17 print("Self-isometries are:", IsomY.isometries(), "\n")
18 print("Isometries Y -> t12072 are:", Y.is_isometric_to(snappy.Manifold('t12072'),
19     return_isometries=True))

```

```

1  Jester knot exterior Y
2  Volume = 7.32772475341775
3  Isometric to census manifold: [t12072(0,0)]
4  Cusp shape = [6.500000000000000 + 4.500000000000001*I]
5
6  Is Y achiral? False
7  Order of isometry group = 4
8  Isometry group =  $\mathbb{Z}/2 + \mathbb{Z}/2$ 
9  Self-isometries are: [0 -> 0
10 [1 0]
11 [0 1]
12 Extends to link, 0 -> 0
13 [1 0]
14 [0 1]
15 Extends to link, 0 -> 0
16 [-1 0]
17 [ 0 -1]
18 Extends to link, 0 -> 0
19 [-1 0]
20 [ 0 -1]
21 Extends to link]
22
23 Isometries Y -> t12072 are: [0 -> 0
24 [1 6]
25 [0 1]
26 Extends to link, 0 -> 0
27 [-1 -6]
28 [ 0 -1]
29 Extends to link, 0 -> 0
30 [1 6]
31 [0 1]
32 Extends to link, 0 -> 0
33 [-1 -6]
34 [ 0 -1]
35 Extends to link]

```

Consequently:

- Y is hyperbolic with $\text{vol}(Y) \approx 7.32772$
- Y is isometric to the 1-cusped census manifold $t12072$

- The cusp shape of Y is $\tau_Y = \frac{13}{2} + \frac{9}{2}i$
- Y admits no orientation reversing self-isometry
- The isometry group of Y has order 4
- Every self-isometry of Y acts trivially on slopes in ∂Y
- Every isometry $Y \rightarrow t12072$ acts on slopes by $(p, q) \mapsto (p + 6q, q)$
- (Basis change) $Y(k, 1)$ is homeomorphic to $t12072(k + 6, 1)$ for each $k \in \mathbb{Z}$

Dunfield [Dun20] determined the exceptional slopes for SnapPy's census manifolds. Exceptional slopes are precisely those yielding nonhyperbolic fillings. For $m137$, the exceptional slopes are

- $(1, 0) \leftrightarrow 1/0 = \infty$ giving $S^1 \times S^2$ upon filling
- $(s, 1)$ where $s \in \{-2, -1, 0, 1\}$

By the basis change, the exceptional slopes of X are

- $(1, 0) \leftrightarrow 1/0 = \infty$ giving $S^1 \times S^2$ upon filling
- $(k, 1)$ where $k \in \{-5, -4, -3, -2\}$

So, the integral exceptional slopes of X are exactly $(k, 1)$ where $k \in \{-5, -4, -3, -2\}$.

For $t12072$, there is a unique exceptional slope

- $(1, 0) \leftrightarrow 1/0 = \infty$ giving $S^1 \times S^2$ upon filling

By the basis change, the exceptional slope of Y is

- $(1, 0) \leftrightarrow 1/0 = \infty$ giving $S^1 \times S^2$ upon filling

So, Y has no integral exceptional slope.

3. EXCEPTIONAL FILLINGS OF THE MAZUR KNOT EXTERIOR

We distinguish the four exceptional fillings $X(k, 1)$, where $k \in \{-5, -4, -3, -2\}$, pairwise up to homeomorphism. To do so, we count equivalence classes of epimorphisms from the fundamental groups $\pi_1(X(k, 1))$ to alternating groups A_n . The GAP command `GQuotients( $G, H$ )` returns a transversal for the equivalence relation on epimorphisms $G \twoheadrightarrow H$ defined by $f_1 \sim f_2$ if and only if there exists an automorphism ϕ of H such that $\phi \circ f_1 = f_2$.

```

1 import snappy
2 from sage.all import gap
3 # Distinguish exceptional fillings of X
4 X = snappy.Manifold('DT: [(14,12,-16,-10,18,-6),(-4,2,8)], [1,1,0,0,0,1,1,0,1]')
5 X.dehn_fill((0,1), 1)
6 X = X.filled_triangulation()
7 for n in range(5, 8):
8     H = gap(f"AlternatingGroup({n})")
9     print(f"Epimorphisms pi_1(X(k,1)) ->> A{n}")
10    for k in range(-5, -1):
11        CX = X.copy()
12        CX.dehn_fill((k,1), 0)
13        G = gap(CX.fundamental_group())
14        Q = gap.GQuotients(G, H)
15        print(f" X({k},1): {len(Q)}")

```

```

1 Epimorphisms pi_1(X(k,1)) ->> A5
2   X(-5,1): 1
3   X(-4,1): 1
4   X(-3,1): 0
5   X(-2,1): 0
6 Epimorphisms pi_1(X(k,1)) ->> A6
7   X(-5,1): 0
8   X(-4,1): 2
9   X(-3,1): 0
10  X(-2,1): 0
11 Epimorphisms pi_1(X(k,1)) ->> A7
12  X(-5,1): 0
13  X(-4,1): 5
14  X(-3,1): 2
15  X(-2,1): 0

```

Table 1 collects the results of this computation. Consequently, the fundamental groups $\pi_1(X(k,1))$ are pairwise nonisomorphic for $k \in \{-5, -4, -3, -2\}$. Therefore, the filled manifolds $X(k,1)$ are pairwise nonhomeomorphic for $k \in \{-5, -4, -3, -2\}$.

	A_5	A_6	A_7
$X(-5,1)$	1	0	0
$X(-4,1)$	1	2	5
$X(-3,1)$	0	0	2
$X(-2,1)$	0	0	0

TABLE 1. Numbers of classes of epimorphisms $\pi_1(X(k,1)) \twoheadrightarrow A_n$.

4. SYSTOLIC GEODESICS

We find all systolic geodesics in the filled manifolds $X(k,1)$ and $Y(k,1)$ for $k \in \mathbb{Z}$. We use a quantitative version of Thurston's hyperbolic Dehn surgery theorem for sufficiently large $|k|$. We cover the remaining finite list of values of k by direct computation.

The quantitative version of Thurston's hyperbolic Dehn surgery theorem that we use requires both the cusp shape and the systole of X and of Y . We computed the cusp shape above. We compute the systole using *m137* and *t12072* since SnapPy seems to perform better with difficult computations using census manifolds. As X and *m137* are isometric, their systoles are equal, and similarly for Y and *t12072*.

```

1 import snappy
2 # Systole of m137 and t12072
3 for name in ["m137", "t12072"]:
4     M = snappy.Manifold(name)
5     g = M.length_spectrum_alt(count=1, verified=True, bits_prec=100)[0]

```

```
6     print(f"sys({name}) =", g.length.real())
```

```
1 sys(m137) = 0.5097911466811016354624?
```

```
2 sys(t12072) = 1.01958229336220327?
```

Consequently, the verified systoles are

$$\text{sys}(X) = \text{sys}(m137) = 0.50979\dots$$

$$\text{sys}(Y) = \text{sys}(t12072) = 1.01958\dots$$

A trailing ? in SnapPy's output indicates that the final digit is uncertain while the preceding digits are verified correct. That yields a rigorous small interval containing the actual value.

Since both systoles exceed 0.145, the hypotheses of Futer–Purcell–Schleimer [FPS25, Thm. 3.19] and [FPS25, Thm. 3.23] reduce to requiring only that the normalized slope length be at least 9.97. Using the cusp shapes

$$\tau_X = \frac{13}{4} + \frac{9}{4}i \quad \text{and} \quad \tau_Y = \frac{13}{2} + \frac{9}{2}i$$

one computes that the normalized length of the filling slope $(k, 1)$ is at least 9.97 whenever $|k| \geq 19$ for X and $|k| \geq 28$ for Y . Therefore, by [FPS25, Thm. 3.23], the core of the filling is the unique systolic geodesic in $X(k, 1)$ for $|k| \geq 19$ and in $Y(k, 1)$ for $|k| \geq 28$.

Now, we check whether the core of the filling is the unique systolic geodesic for the remaining finite list of manifolds $X(k, 1)$ with $|k| \leq 18$. We perform the check using $m137$ and translate the results to X using the basis change. We must check the list $m137(s, 1)$ for $-15 \leq s \leq 21$. We compute the larger list $|s| \leq 25$ for overlap.

For $m137$, the ordinary routine `length_spectrum` occasionally succeeds when the verified routine `length_spectrum_alt` cannot certify the hyperbolic structure. Accordingly, we first attempt `length_spectrum` and fall back to `length_spectrum_alt`. For $t12072$, the verified routine succeeds throughout, so only `length_spectrum_alt` is needed.

```
1 import snappy
2 # Compare the filling core with the systole and test uniqueness for m137(s,1)
3 print(f"{'s':^3} {'core':^12} {'systole':^12}"
4       f"{'core=systole?':^15} {'unique?':^8}")
5 print("-" * 56)
6 for s in range(-25, 26):
7     if s in {-2, -1, 0, 1}:
8         print(f"{s:3d} {'----':>12} {'----':>12} {'nonhyperbolic':>15}")
9         continue
10    M = snappy.Manifold(f"m137({s},1)")
11    core = M.cusp_info(0).core_length.real()
12    try:
13        LS = M.length_spectrum(1.5, include_words=True)
14        systole = LS[0].length.real()
15        unique = abs(LS[0].length.real() - LS[1].length.real()) > 1e-10
16    except RuntimeError:
```

```

17     LS = M.length_spectrum_alt(count=4, verified=True, bits_prec=200)
18     systole = LS[0].length.real().center()
19     ordinary = [g for g in LS if g.core_curve is None]
20     unique = ordinary[0].length.real().upper() < \
21         ordinary[1].length.real().lower()
22     core_is_systole = abs(core - systole) < 1e-10
23     print(f"{s:3d} {core:12.8f} {systole:12.8f}"
24           f"{str(core_is_systole):^15} {str(unique):^8}")

```

Consequently, the following hold for $m137(s, 1)$:

- For $s \notin \{-4, -3, \dots, 3\}$, the core of the filling is the unique systolic geodesic
- For $s \in \{-4, -3, 2, 3\}$, the systolic geodesic is not the core of the filling but is unique
- $s \in \{-2, -1, 0, 1\}$ are the exceptional slopes

Therefore, the following hold for $X(k, 1)$:

- For $k \notin \{-7, -6, \dots, 0\}$, the core of the filling is the unique systolic geodesic
- For $k \in \{-7, -6, -1, 0\}$, the systolic geodesic is not the core of the filling but is unique
- $k \in \{-5, -4, -3, -2\}$ are the exceptional slopes

Now, we check whether the core of the filling is the unique systolic geodesic for the remaining finite list of manifolds $Y(k, 1)$ with $|k| \leq 27$. We perform the check using $t12072$ and translate the results to Y using the basis change. We must check the list $t12072(s, 1)$ for $-21 \leq s \leq 33$. We compute the larger list $|s| \leq 35$ for overlap.

```

1 import snappy
2 # Compare the filling core with the systole and test uniqueness for t12072(s,1)

Consequently, the following hold for $t12072(s, 1)$:

- For $s \notin \{-3, -2, \dots, 3\}$, the core of the filling is the unique systolic geodesic
- For $s \in \{-3, -2, \dots, 2\}$, the systolic geodesic is not the core of the filling but is unique
- For $s = 3$, the core of the filling is a systolic geodesic but it is not unique

Therefore, the following hold for $Y(k, 1)$:

- For $k \notin \{-9, -8, \dots, -3\}$, the core of the filling is the unique systolic geodesic

- For $k \in \{-9, -8, \dots, -4\}$, the systolic geodesic is not the core of the filling but is unique
- For $k = -3$, the core of the filling is a systolic geodesic but it is not unique

5. DRILLING SYSTOLIC GEODESICS

Drilling unique systolic geodesics is a powerful method for producing topological invariants. We drill the unique noncore systolic geodesics for the hyperbolic filled manifolds $X(k, 1)$ and $Y(k, 1)$. For $Y(-3, 1)$, we show there are exactly two systolic geodesics and drill each of them. We compute with $m137(s, 1)$ and $t12072(s, 1)$ and translate the results to $X(k, 1)$ and $Y(k, 1)$ using the basis changes.

```

1 import snappy
2 # Drill the unique systolic geodesic for the remaining
3 # hyperbolic fillings of m137(s,1)
4 print(f"{'s':^3} {'systole':^12} {'systole drilled manifold'}")
5 print("-" * 82)
6 for s in [-4, -3, 2, 3]:
7     M = snappy.Manifold(f"m137({s},1)")
8     D = M.drill(0)
9     D.dehn_fill((1,0),1)
10    F = D.filled_triangulation([0])
11    g = F.length_spectrum_alt(count=1, verified=True, bits_prec=200)[0]
12    H = F.drill_word(g.word, verified=True, bits_prec=200)
13    print(f"{s:3d} {g.length.real():12.8f} {H.identify()}")

```

s	systole	systole drilled manifold
-4	0.59995705	[m081(0,0)]
-3	0.49916351	[m011(0,0)]
2	0.36613070	[m004(0,0), 4_1(0,0), K2_1(0,0), K4a1(0,0), otet02_00001(0,0)]
3	0.56397216	[m038(0,0)]

```

1 import snappy
2 # Drill the unique systolic geodesic for the remaining
3 # hyperbolic fillings of t12072(s,1)
4 print(f"{'s':^3} {'systole':^12} {'systole drilled manifold'}")
5 print("-" * 67)
6 for s in [-3, -2, -1, 0, 1, 2]:
7     M = snappy.Manifold(f"t12072({s},1)")
8     g = M.length_spectrum(2.0, include_words=True)[0]
9     H = M.drill_word(g.word)
10    print(f"{s:3d} {g.length.real():12.8f} {H.identify()}")

```

s	systole	systole drilled manifold
-3	0.77858590	[v3519(0,0)]
-2	0.67096709	[v3200(0,0)]
-1	0.61977976	[v2919(0,0)]
0	0.61870851	[v2911(0,0)]
1	0.66785203	[v3184(0,0)]
2	0.77442060	[v3505(0,0), 8_21(0,0), K7_127(0,0), K8n2(0,0)]

Consequently, we obtain the drilled manifolds in Table 2.

$X(k, 1)$		$Y(k, 1)$	
k	Systole-drilled manifold	k	Systole-drilled manifold
-7	$m081$	-9	$v3519$
-6	$m011$	-8	$v3200$
-5, ..., -2	exceptional slopes	-7	$v2919$
-1	$m004$	-6	$v2911$
0	$m038$	-5	$v3184$
otherwise	$m137$	-4	$v3505$
		-3	not unique
		otherwise	$t12072$

TABLE 2. Manifolds obtained by drilling the unique systolic geodesic in $X(k, 1)$ and $Y(k, 1)$.

Now, we show that $Y(-3, 1)$ contains exactly two systolic geodesics and we drill each of them. We thank Nathan Dunfield for this code.

```

1 import snappy

```

The verified length spectrum of $t12072(3,1)$ begins with two geodesics, Cusp 1 and Cusp 0, with apparently equal lengths. Drilling each of them yields $t12072$. Drilling both of them yields a two-cusped manifold with a self-isometry—the first isometry listed—interchanging the cusps and preserving the meridians up to orientation. Consequently, $t12072(3,1)$ has a self-isometry interchanging the geodesics Cusp 1 and Cusp 0. Therefore, Cusp 1 and Cusp 0 are the two systolic geodesics of $t12072(3,1)$. It follows that $Y(-3,1)$ contains exactly two systolic geodesics and drilling each of them yields $t12072$.

We verify that the 12 drilled manifolds are pairwise nonhomeomorphic. By Mostow–Prasad rigidity, it suffices to show they are pairwise nonisometric.

```

1 import snappy
2 # Verify the 12 systole drilled manifolds are distinct
3 names = ["m137", "t12072", "m081", "m011", "m004", "m038",

64	Verify $\text{vol}(Y(k,1))=\text{vol}(Y(-k-13,1))$ for $-1000\leq k\leq 1000$:			
65	True			

Consequently, we conjecture that:

- $\text{vol}(Y(k,1)) = \text{vol}(Y(-k-13,1))$ for all $k \in \mathbb{Z}$
